MASTER'S THESIS

Exploring the relationship between Hawkes processes and self-organized criticality in living systems

Antonio Rivas Blanco

Tutor(s): Jorge Hidalgo Aguilera and Serena di Santo

Line of research: Modelling of complex systems and their interdisciplinary applications

Córdoba, 07/2024

Autorización de defensa del Trabajo Fin de Máster

Tutor 1: Jorge Hidalgo Aguilera
Tutor 2: Serena di Santo

INFORMAN: Que el presente trabajo titulado *Exploring the relationship between Hawkes processes and self-organized criticality in living systems* que constituye la memoria del Trabajo Fin de Máster ha sido realizado por Antonio Rivas Blanco y AUTORIZA/N su presentación para que pueda ser defendido en la convocatoria 1ª con fecha 23/07/2024.

Firmado en Córdoba a X de julio de 2024

Tutor 1: Jorge Hidalgo Aguilera

Tutor 2: Serena di Santo

Declaración de autoría

Nombre y apellidos: Antonio Rivas Blanco
DNI: 49832223D

DECLARA

1. Que el trabajo que presenta es totalmente original y que se hace responsable de todo su contenido.
2. Que no ha sido publicado no total ni parcialmente.
3. Que todos los aportes de otros autores/as han sido debidamente referenciados.
4. Que no ha incurrido en fraude científico, plagio o vicios de autoría.
5. Que, en caso de no cumplir los requerimientos anteriores, aceptará las medidas disciplinarias sancionadoras que correspondan.

Abstract

Chapter 1

Introduction

Chapter 2

Objectives

Ordenar los objetivos una vez escrito el trabajo para que coincidan con como se presenta.

The main objectives of this Master's thesis are:

- To understand what Hawkes processes are, where we can find them, how to generate them computationally and relate them with neuroscience.
- To understand the importance of time binning and reproduce the results of the original paper [1] and compare them with the results obtained in this work.
- ¿Criticality?
- To study the behaviour of a self-exciting process with $n = 2$ and compare it with the case $n = 1$.
- To study the behaviour of an inhibitory and excitatory neuron coupled.

Chapter 3

Methodology

Chapter 4

Results

This section provides the main results of the investigation. First, the results reproduced from the original paper [1] are presented. Then, the results of the analysis with $n = 2$ are shown. Finally, we have studied the behaviour of an inhibitory and excitatory neuron coupled.

4.1 Results from the original paper

The first result is the percolation phase diagram is shown in Figure 4.1. It displays the percolation strength P_∞ versus the resolution parameter Δ.

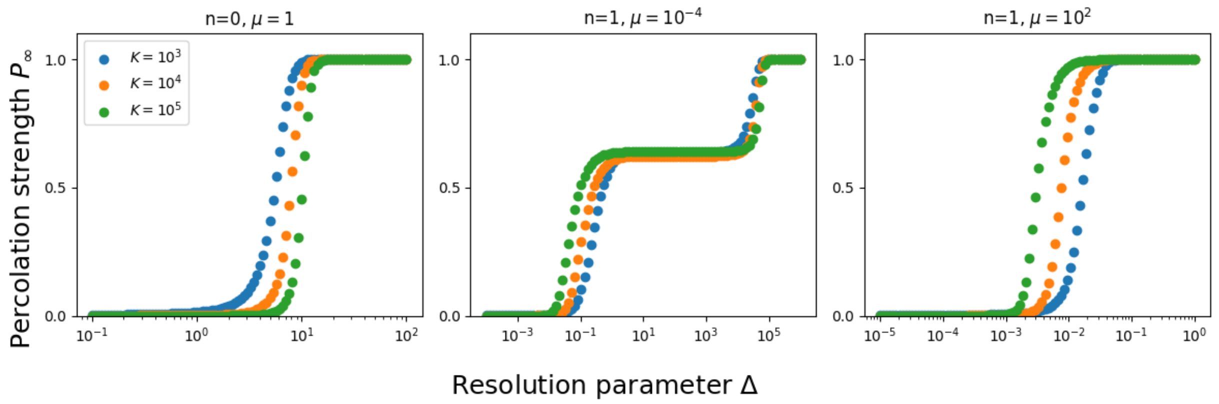

Figure 4.1. Percolation phase diagrams for different event number K taking average values of $R = 1000$ realizations.

The first plot configuration is a Markovian ($n = 0$) Poisson process with rate μ. This is the simplest case, where the inter-event time $x = t_i - t_{i-1}$ follows an exponential distribution $P(x_i) = \mu e^{\mu x_i}$. The other two plots are non-Markovian Hawkes processes for $\mu \ll 1$ and $\mu \gg 1$. In one hand, a double transition is observed when $\mu = 10^{-4}$, in the other hand, a single transition occurs when $\mu = 10^2$.

Once we have the phase diagram, we can study avalanche statistics. Given a resolution parameter Δ, we can spot clusters or avalanches of activity. A cluster starts when a neuron fires and ends if the neuron does not fire for a time greater than Δ. We define the size of a cluster as the number of spikes it contains and the duration as the time between the first and last spike. We have studied the avalanches for $K = 10^5$ events and $R = 1000$ realizations to obtain the average values since the process is highly not stationary. We will study the size and duration of the avalanches for the three different regions of the phase diagram for $\mu = 10^{-4}$ and the two regions of the phase diagram for $\mu = 10^2$. These regions are separated by two thresholds, a pseudocritical threshold Δ_1^* and the threshold of the second transition at Δ_2^*. We can compute these with the following formulas [1]:

$$\Delta_1^* \simeq \frac{log(K)}{\langle\lambda\rangle} = \frac{log(K)}{\mu + \sqrt{2\mu K}} \tag{4.1}$$

$$\Delta_2^* = \frac{log(K)}{\mu} \tag{4.2}$$

Once we have the thresholds, we can study the avalanches for the different regions of the diagram. The results are shown in Figure 4.2.

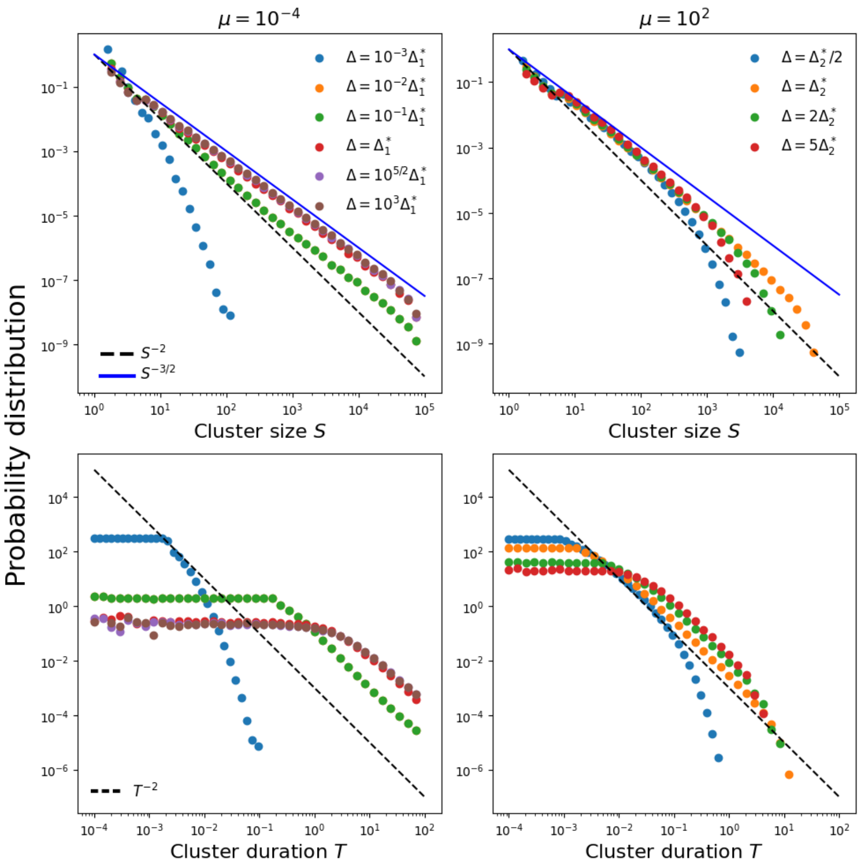

Figure 4.2. Avalanche statistics for a self-exciting Hawkes process with $n = 1$ for $K = 10^5$ events averaged over $R = 1000$ realizations.

For $\mu = 10^{-4}$, the results show a power-law distribution for the size and duration of the avalanches . In the case of duration, the exponent is $\tau = 2$ and for the size, we can notice a transition of the exponent from $\alpha = 2$ to $\alpha = 3/2$ as we increase the resolution parameter Δ. The first exponent corresponds to the universality class of 1D percolation, whereas the second is compatible with the universality class of mean-field branching process. However, if $\Delta \ll \Delta_1^*$, the behaviour is subcritical for the size and duration of the avalanches.

For $\mu = 10^2$, the result shows another power-law distribution for both size and duration of the avalanches unless $\Delta \ll \Delta_2^*$, where the behaviour is subcritical. . In this case, the exponents are $\alpha = \tau = 2$ corresponding to the universality class of 1D percolation.

4.2 Results for n=2

In the article, the authors have studied a process which is critical itself because the parameter n is fixed to $n = 1$. We have studied the case $n = 2$ to see if the process is still critical. In the Figure 4.3

two time series for $n = 1$ and $n = 2$ are shown.

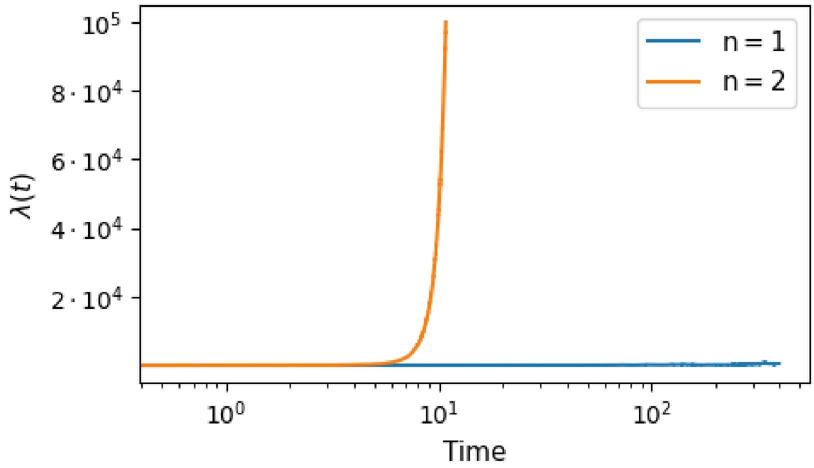

Figure 4.3. Time series for $n = 1$ and $n = 2$.

Similarly to the previous section, first we obtain the phase diagram in order to observe the transitions. In this case, Eqs 4.1-4.2 are not valid. Therefore, we will obtain this parameter graphically from the phase diagrams shown in Figure 4.4.

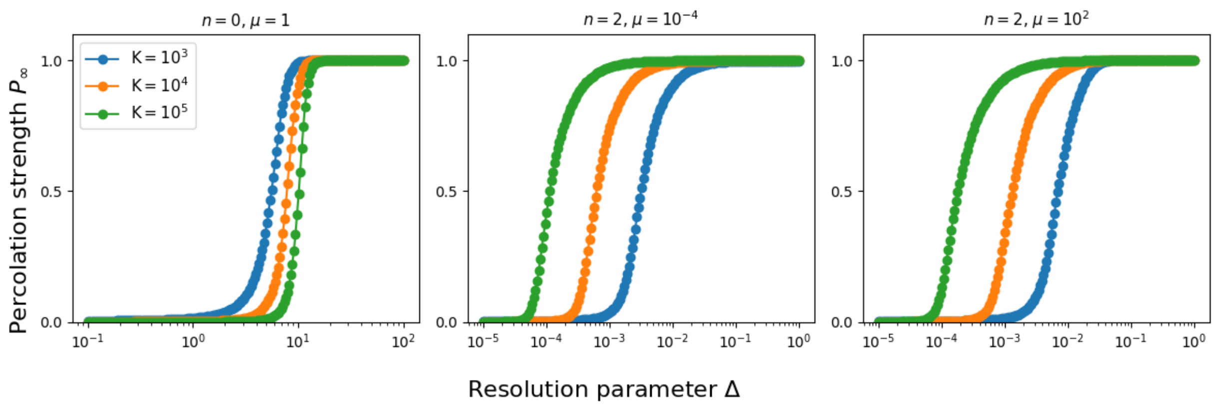

Figure 4.4. Percolation phase diagrams for a Hawkes process with $n = 2$.

As we can see, now we have a single transition for $\mu = 10^{-4}$ and $\mu = 10^2$ corresponding to 1D percolation, consequently, the exponents for the size and duration should be $\alpha = \tau = 2$. In a similar way, we have studied the avalanches for $K = 10^5$ events and $R = 1000$ realizations to obtain the average values. The statistics of the avalanches are shown in Figure 4.5.

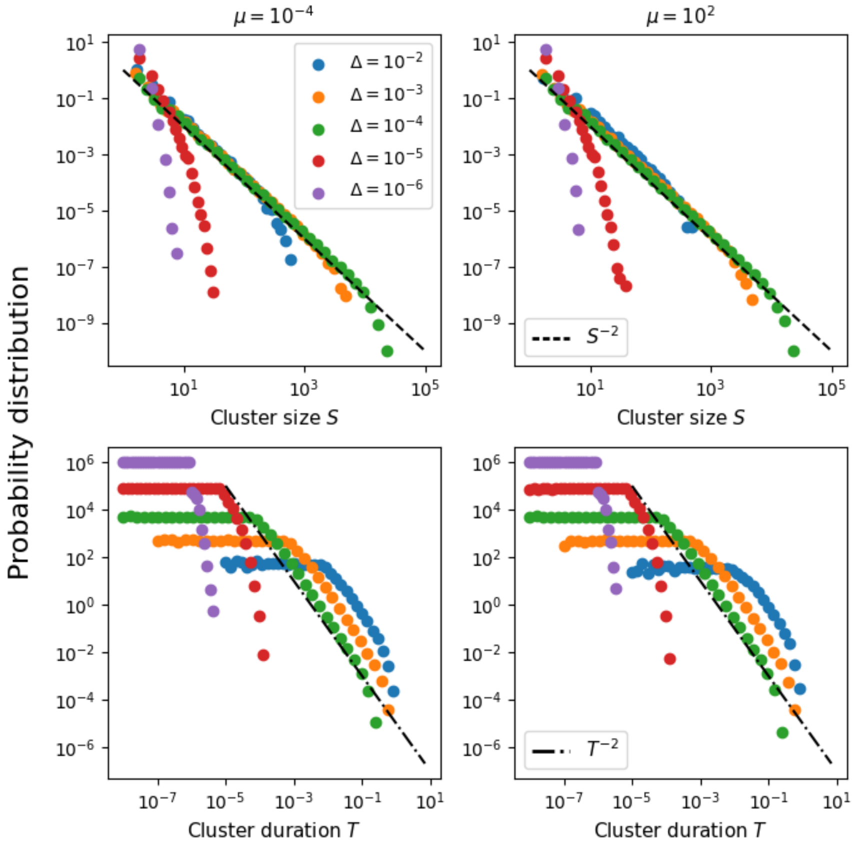

Figure 4.5. Avalanche statistics for a self-exciting Hawkes process with $n = 2$ for $K = 10^5$ events averaged over $R = 1000$ realizations.

4.3 Inhibitory and excitatory neurons coupled
